

Balancing Complexity and Personalization

Personalized Medicine vs. One-Size-Fits-All

Multi-model Sequential Decision Models for Chronic Disease Management

Personalized Medicine

Intro

What is it?

- Tailors medical care to individual characteristics
- Demographics, life-style, genetics, etc.

Alternative

- One size fits all.

Benefits

- Improves patient outcomes
- Improves equality in care outcomes

Operational complexities

- Hard to implement
- Training burden
- Risk of inconsistency

Research question

Optimal balance: trade-off

More personalization:

- ↑ effectiveness
- ↑ Fairness and equity in care outcomes
- ↑ complexity
 - ↓ efficiency

Potential solution

- Create a manageable number of patient groups
 - Handful of policies

Nested optimization

- Aggregate population into k groups
- Optimize and apply the *same* treatment strategy for a given group
 - Multi-model optimization

Benefits:

- Simplify clinical decision-making
 - Reduce complexity
- Preserves *some* level of personalization

But...

- May lead to inequality of health outcomes

Research question

Optimal balance

Current aggregation methods

- Based on clinical **intuition** rather than data/evidence
 - Based on disease prognosis
 - Intuition is often unaligned with operational decision
 - May overlook fairness and introduce disparities/bias

Proposed Strategy

- Create optimal clustering of patient profiles
 - Interpretable, systematic, and data-driven
- Consider fairness
 - Minimize deviations from care targets
 - timely treatment delivery

Case study

- Head and neck cancer
- Optimal post-treatment monitoring
- Care target
 - Cancer recurrence detection delay

Clinical context

Clinical context

Head and neck cancer

Incidence/prevalence

- 1 million *new* cases world-wide, annually
- 3rd most common cancer
 - HPV pandemic

Recurrence

- 50% one-year mortality in case of recurrence
 - Loco-regional or distant metastasis

Mortality and recurrence

- Demographics
- Disease history
- Lifestyle

Heterogeneity:

- 5-year recurrence rate:
 - Between 6% to 60%

Clinical context

Pathways

Frequent monitoring

- Inform on patient's current health
- Inform on disease progression
 - Revise surveillance plan

Benefits

- Early detection
- Improved survival
 - 4 weeks reduction in delay
 - 10% less mortality
- Improved quality of life

Challenges:

- Capacity constraints
- Economic burden
- Adverse patient outcomes
 - Stress: false-positives
 - Inconvenience and pain
 - Exposure to radiation

Clinical context

Pathways

CT-Scan

- Costly
- High false-positive/negative rate
- *Pinpoints recurrence location*
 - Loco-regional or metastasis

Newer technology: ctDNA

- Simple blood test
- Cheaper
- Ease of access and implementation
- Improved adherence
- High accuracy (sensitivity, specificity)
- Detect radiologically occult (undetectable) recurrence
 - 4 Mo in advance
- *Cannot delineate loco-regional or metastasis*

Research gap

Operational question

How to integrate ctDNA?

- No data-driven guideline

Operational questions:

Timing

- First test
- Subsequent tests

Modality

- ctDNA or CT scan?

Respond to test result

- Confirmatory tests
 - CT to localize
 - Biopsy to confirm
- Revise test schedule

Evaluation of status-quo.

Clinical context

Current guidelines

NCCN guideline, v1.2021:

- PET/CT scan: 3 Mo
- CT scan: 6 Mo, 9 Mo, 1 Y, 18 Mo, 2 Y, 3 Y

eviCore guideline, v2.1 :

- PET/CT scan: 3 Mo
- CT scan : 6 Mo, 1-3 Y

Kowalchuk et al. 2023:

- ctDNA: every 3 Mo, in years 1-2

Berger et al. 2022:

- ctDNA: every 3 Mo in years 1–2
- ctDNA: every 6 Mo in years ≥ 3

Clinical context

Evaluation

Outcomes

- System outcome
 - Testing cost
- Patient outcomes
 - Recurrence detection delay
 - False positive rate

Method

- Monte-Carlo simulation

Disease model

- Beesley et al. 2021
- Multi-state continuous-time semi-Markov model

Evaluation

Hidden Semi-Markov model

Evaluation

Hazard ratios

Clinical context

NCCN Guideline Evaluation

Testing cost

- \$26,700 per patient

False positive rate

- 56%

Recurrence detection delay

- Approx. 6 Mo
- Care target for personalizing

Optimize monitoring guideline

Optimization model

Personalized model

Epochs:

- Monthly

Actions:

- CT scan
- DNA test
- Wait

Horizon:

- 3-5 years

Objective:

- Minimize monitoring cost

Constraint:

- Recurrence detection delay:
- Target: 6 Mo

Model:

- Partially observable Markov Decision model
- Constrained POMDP

Optimization model

Personalized model

Core states

- Hidden:
 - Recurrence-free
 - Loco-regional recurrence
 - Metastatic recurrence
- **Death**

Optimization model

Personalized model

Markov model

- Converted semi-Markov model to an *equivalent* Markov model
 - Match occupancy measures
 - Non-stationary core state transitions

Multi-reward Markov model

- Monitoring costs
- Delay costs
 - One time unit for being in recurrence states, undetected

Constrained POMDP Solution

- Weighted sum of the two objectives
- Fine-tune the weight to match the target delay
 - Apply binary search

Personalized model

Optimal policy

CT-scan ctDNA Wait

$[N, L, M] = [30\%, 50\%, 20\%]$

Personalized model

Optimal policy

CT-scan ctDNA Wait

Year 1

Year 2

Year 3

Personalized model

Policy in action

Observation

- Only DNA test until test becomes positive

Implications

- POMDP policy can be converted to a DNA test schedule
- Use DNA test to detect recurrence, use CT scan to pinpoint

Why?

- Higher sensitivity/specificity
- *Cost-effective*

Personalization and trade-off

Optimization model

Personalized model

6 Categorical variables:

- Sex: 2
- ACE: 5
- Anemia 2
- Smoking: 2
- Cancer stage: 12
 - T: 4
 - N: 3

1 Continuous variable:

- Age
- Categorize: <52 Y, ≥ 52 Y

Challenges:

- ≥ 960 total policies
- Hard to implement
- Diminishing return in additional stratification

Optimization model

Trade-off

Balancing objective:

- # of policies
- Inequality of patient outcomes
 - Detection delay target: 6 Mo
 - Loss: **positive** deviation from target
 - Weighted average **positive** deviation from target

Approach:

- Optimal sub-population aggregation
 - Optimal structured set partitioning
 - Interpretable

Trade-off model

Population partitioning

Unstructured partitioning

- Assignment
 - Patients to partitions

All patient profiles

Structured partitioning:

- Based on covariates
- Follow a decision tree
- Interpretable/explainable

Trade-off model

Nested optimization

1. Choose partitions

2. For each partition: solve multi-model CPOMDP:

- Each patient profile, one model
 - Hence multi-model CPOMDP
- One policy across all models
 - Policy agnostic to stochastic process differences
- Minimize average partition cost
 - Constraint: *average within-partition* delay ≤ 6 Mo

Solution:

- Mixed integer LP

Trade-off model

Partitioning loss

Outcome

- Inequality of patient outcomes
 - Weighted average **positive** deviation
 - Patient profile weight in the population

Mathematical model:

$$\min_{Q, \pi_{\mathcal{P}}^*} \sum_{\mathcal{P} \in Q} \sum_{x \in \mathcal{P}} w_x \cdot \left(d_x^{\pi_{\mathcal{P}}^*} - \bar{d} \right)^{+}$$

Trade-off model

Within-partition optimization

Multi-model CPOMDP

Multi-model optimization

- Uncertain model parameters
 - Limited data, system changes
- Heterogenous dynamics/population

Mathematical modeling:

- Two stage stochastic optimization
 - Stage 1: fix action
 - Stage 2: true model unravels
- Robust and non-robust objectives

Trade-off model

Within-partition optimization

Multi-model MDP

- Admits deterministic policies
- Mixed integer linear programming
 - Stage 1: decide actions per state/time
 - Stage 2: determine value functions

Multi-model POMDPs

- Uncountable belief states

Approximation methods

- Create a *population* core state transition matrices
 - Weighted average

Bayes-adaptive approach

- Distribution weight in period 1
- Occupancy informed Bayes-adaptive weights thenceforth
- Reproduce the same occupancy measures in expectation

Tractability and Approximation Methods

Trade-off model

Problem complexity

Problem is intractable

Unstructured partitioning

- NP-complete
 - Many cases NP-hard.
- Require exponential # of costs
 - For all partitioning configurations

Partitioning costs

- Multi-model MDP is NP-Hard
 - Steimle et al. 2021
- Our case: constrained POMDP

Structured partitioning

- Partitioning follows decision tree

Approximation methods

Solution approach: clustering

Interpretable clustering

- Partition to k clusters minimizing *average dissimilarity*

Clustering idea

- Aggregate based on *similarity* in stochastic process
 - Hazard ratio vector
 - Average core-state transition probabilities
 - Bayesian core-state transition probabilities

Clustering loss:

- Distance from cluster's focal point

Approximation methods

Solution approach: partitioning

Partitioning idea

- Aggregate based on *consequence* of aggregation of profiles
- Loss: deviation from target when merged into a partition

Inputs:

- Profile covariate matrix, binary
- Profile weights in the population
- *Pairwise* distance matrix

Objective:

- Partition to k groups minimizing *inequality proxy*

Partitioning idea

Distance matrix

Pairwise distance matrix:

- Create a 2-member partition with profiles i, j
- Solve a bi-model CPOMDP
- Evaluate optimal policy
 - Calc detection delay d_i, d_j

Cost of aggregating i, j :

- $d_{ij} = (d_i - \bar{d})^+$
- $d_{ji} = (d_j - \bar{d})^+$

Partitioning idea

Inequality proxy

Objective:

- Minimize weighted average of inequalities
- Across all patients

$$\min \sum_i w_i \hat{\delta}_i$$

Per partition:

- Weighted average of distance
 - From partition members
- Partition weights normalized to 1: w'_j
- Inequality proxy:

$$\hat{\delta}_i = \sum_{j \in \mathcal{P}} w'_j d_{ij}$$

Approximation methods

Optimization approach

Model:

- Adaptation of Bertsimas and Dunn (2017)
- Optimal binary tree
 - Mixed integer linear programming model
 - Local search: non-linear objectives

Model decides:

- Tree configuration
 - Branching
 - Each leaf is a partition/cluster
- Constrain or penalize # of leaves

Partitioning idea

Policies

Robust objectives

- Max of max-deviations (worst case)
- Simple average of max-deviations
- Weighted-average of max-deviations

Non-robust objectives

- Average of Average deviations: simple average
- Weighted average of weighted average deviations

Clustering idea

Similarity targets

Similarity in stochastic process

- Hazard ratio vector
- Average core-state transition probabilities
- Bayesian core-state transition probabilities

Similarity in optimal policy

- WIP

$k=3$

Results

Optimal partitions, $k=2$ to 4

$k=4$

Limitations

Computations:

- Time-consuming for large tree depth

Approximation:

- Proxy vs real objective
- CPOMDP
- Multi-model CPOMDP

Data and evidence:

- Disease model
 - More stratification, less data, less confidence
- Confidence in test performance

Conclusion

Challenge:

- Trade-off
 - personalized care vs one-size-fits-all
 - Complexity vs fairness

Solution:

- Strategic population stratification/aggregation
- Data-driven and systematic
- Interpretable
- optimal tree-based partitioning

Case study:

- post-cancer surveillance
- generalizable beyond the case study

Takeaway

Smart design of population aggregation/stratification enhances healthcare delivery by balancing personalization, interpretability, and equality.
